The Long QT Syndrome
A Guide for Patients and Health Care Providers

Why do I need to know about the Inherited Long QT syndrome?
What Physicians need to know
What Patients and Parents need to know

The Sudden Arrhythmia Death Syndromes (SADS) Foundation is a leader in education, research and advocacy. Our Mission is to save the lives and support the families of children & young adults who are genetically predisposed to sudden death due to heart rhythm abnormalities.

Why do I need to know about the Inherited Long QT syndrome?

We provide this information with the hope that informing physicians, other health care providers, and the public will encourage early and correct diagnosis and proper therapies, resulting in the reduction and ultimate elimination of cardiac arrest and sudden death from inherited long QT syndrome (LQTS).

What Physicians need to know:

• When to consider LQTS as a possible diagnosis.
• When to refer patients for diagnosis & treatment.
• About genetic testing for LQTS and other SADS conditions.
• How to develop a family pedigree and screen family members for LQTS.

Patients and Parents need to know:

• The warning signs and symptoms of LQTS.
• Who to see for proper testing.
• How to protect their children and themselves.
• How to expand their family pedigree and contact other family members who may be at risk.

What is LQTS?
LQTS is a disturbance of the heart’s electrical system. It is caused by abnormalities of microscopic pores (proteins) in the heart cells called ion channels. Ions such as potassium, sodium, calcium and chloride pass back and forth across the cell membrane through ion channels. As they do, these ion channels generate the electrical activity (depolarization and repolarization) that controls the heart’s beating. Our window to this electrical activity of the heart is through an electrocardiogram (ECG or ECG). Potassium and

The Sudden Arrhythmia Death Syndromes (SADS) Foundation is a leader in education, research and advocacy. Our Mission is to save the lives and support the families of children & young adults who are genetically predisposed to sudden death due to heart rhythm abnormalities.

What is the treatment and who should be treated?

All symptomatic patients should receive treatment. All children and young adults should be treated even if they do not have symptoms. This is because symptoms might occur and sudden death may be the first symptom. At present, it is not possible to tell which child or youth is destined to have symptoms. Thus, preventative treatment is required in all. The usual treatment involves taking beta-blocker medications daily. This approach is effective for the majority of patients with LQTS. The dose needs to be monitored closely, balancing the prevention of LQTS spells with unwanted side effects related to energy level and mood.

Patients - who continue to have symptoms in spite of appropriate doses of beta-blockers or are not able to tolerate their beta-blocker therapy - may also require additional medications or devices. Patients who have experienced a cardiac arrest usually receive an ICD (implantable defibrillator). With LQTS genetic testing, treatment strategies can be guided by the underlying genetic cause. For example, beta-blockers are generally extremely protective in type 1 LQTS (LQT1) but may not afford sufficient protection in type 3 LQTS (LQT3). Left cardiac sympathetic denervation (LCSD) surgery is available in a few LQTS centers providing another important treatment option for those patients who have either experienced appropriate ICD shocks or not tolerating their medications because excessive side effects who have either experienced appropriate ICD shocks or not tolerating their medications because of excessive side effects.

Persons over 40 years of age at the time of diagnosis, who have been asymptomatic (without symptoms) all their life (or for many, many years), may not need treatment, as their risk of developing symptoms or cardiac events while on medication may be that the medication has been misused or stopped.

How can parents protect their kids?

• Make sure the children take their medications daily, with missing doses.
• See the doctor regularly for follow-up. Growing children need medication dose changes regularly. Make sure you see the doctor at least once a year, more frequently during very rapid growth, and discuss the need for dose changes.
• Be supportive if the doctor advises “no competitive sports for your child”. Support this advice, and help the child to understand that usual physical activities are suitable, but that competition may be dangerous. Channel their energies into sports without intense physical demands (golf, for example), or non-physical activities.
• Insist upon a “QT safety check” with any prescription given to your child. Besides the provided list of at-risk medications, the physician ordering the medication and the pharmacist dispensing it should conduct their own surveillance.
• Get additional medical advice if you are not comfortable with how things are going. Ideally, every patient/family with LQTS should be cared for by a heart rhythm specialist (cardiac electrophysiologist) or even a long QT syndrome specialist. Do not hesitate to obtain a second opinion if you have any questions about your or your child’s treatment.
• Make sure your family has an AED (automatic external defibrillator) and/or your child’s school district has AED programs in their schools.

What is LQTS?
LQTS is a disturbance of the heart’s electrical system. It is caused by abnormalities of microscopic pores (proteins) in the heart cells called ion channels. Ions such as potassium, sodium, calcium and chloride pass back and forth across the cell membrane through ion channels. As they do, these ion channels generate the electrical activity (depolarization and repolarization) that controls the heart’s beating. Our window to this electrical activity of the heart is through an electrocardiogram (ECG or ECG). Potassium and
About 90% of people have a value between 380 and 440 ms. To determine if a given QT is normal for a given heart rate, it is necessary to consider the "recharging" process and the QT interval, thus predisposing patients to certain cardiac arrhythmias. Thus, LQTS is a glitch in the electrical recharging phase of the heart.

What is the QT interval?

The QT interval is a time interval on the ECG. It represents the time from the heart's pumping chambers (ventricles), to the end of the electrical recharging of the heart (repolarization). It is measured in milliseconds and slowly approximates the time from the beginning of the ventricles' contraction until the end of relaxation.

The QT interval varies in each person and between persons, and is most physiologic parameters, such as blood pressure or heart rate. In particular, the QT varies with the heart rate. It shortens as the rate increases and lengthens as the rate decreases. Therefore, there is a range of normal or healthy QT intervals. In contrast, the long QT heart often recharges sluggishly or inefficiently as evidenced by a "prolonged QT interval" on the ECG. To determine if a given QT is normal for a given heart rate, the QT is corrected for the heart rate using a simple mathematical formula, and the resultant quantity is called the QTc. The QTc is the value that doctors generally use when assessing for LQTS.

The normal QTc interval varies from approximately 0.350 to 0.480 milliseconds. Probably less than 1% of the population has a QTc < 0.350 ms or a QTc > 0.480 ms. About 90% of people have a value between 0.380 and 0.440 ms, which is the range doctors generally consider as the "normal" range. However, this "normal" range is affected by age and gender. For example, women tend to have slightly longer QTc intervals than men. While a QTc of 0.440 ms represents the top 2.5 percentile in a 4-day-old infant, this same QTc value is seen in 10–20% of postpubertal women.

What is the QT interval?

The QT interval is a time interval on the ECG. It represents the time from the heart's pumping chambers (ventricles), to the end of the electrical recharging of the heart (repolarization). It is measured in milliseconds and slowly approximates the time from the beginning of the ventricles' contraction until the end of relaxation.

The QT interval varies in each person and between persons, and is most physiologic parameters, such as blood pressure or heart rate. In particular, the QT varies with the heart rate. In contrast, the long QT heart often recharges sluggishly or inefficiently as evidenced by a "prolonged QT interval" on the ECG. To determine if a given QT is normal for a given heart rate, the QT is corrected for the heart rate using a simple mathematical formula, and the resultant quantity is called the QTc. The QTc is the value that doctors generally use when assessing for LQTS.

The normal QTc interval varies from approximately 0.350 to 0.480 milliseconds. Probably less than 1% of the population has a QTc < 0.350 ms or a QTc > 0.480 ms. About 90% of people have a value between 0.380 and 0.440 ms, which is the range doctors generally consider as the "normal" range. However, this "normal" range is affected by age and gender. For example, women tend to have slightly longer QTc intervals than men. While a QTc of 0.440 ms represents the top 2.5 percentile in a 4-day-old infant, this same QTc value is seen in 10–20% of postpubertal women.

The diagram below provides an example of a normal and prolonged QTc.

When should the diagnosis be suspected?

- In any young person with unexplained syncope (fainting), unexplained seizures, or unexplained cardiac arrest or sudden death.

Usually, a careful history of the events surrounding the syncopal differentiation LQTS-induced syncope from normal faint, known as vasovagal or neurocardiogenic syncope. The LQTS faint is usually precipitous and without warning. It often occurs during or just after physical exertion, emotional excitement or sudden auditory arousal (such as a doorbell or alarm clock), but may occur during sleep or at rest. Conversely, in vasovagal syncope, most times there are warning symptoms, such as dizziness, blurring or blackening of vision, tingling or sweating, for seconds to even minutes prior to the syncope. Also, a precipitating event is usually present, commonly pain, injury, nausea, or an unpleasant or stressful experience.

- When there is a family history of unexplained syncope, unexplained seizures, or sudden death in young people. As noted above, at least one-third to one-half of individuals never exhibit symptoms, and, therefore, the lack of prior symptoms does not exclude a person or family from having LQTS.

- When the autopsy is normal following the sudden and unexpected death of a young person.

How is the diagnosis made?

LQTS is diagnosed primarily upon recognition of a prolonged QT interval on the ECG. A QTc of 0.470 milliseconds (ms) in males and 0.480 ms in females is generally considered strongly suspicious for LQTS. In the absence of medications, which prolong the QT interval or other forms of heart disease. A QTc of less than 0.400 ms in males and 0.410 ms in females makes the diagnosis unlikely. The computer generated QTc may be incorrect, so when the diagnosis of LQTS is considered, the physician should verify the computer measurement.

Not all LQTS patients have a prolonged QTc on the initial ECG, however. In fact, about 30–50% have a QTc that overlaps with the normal range and over 10% have a QTc < 0.440 ms. QTc’s in this range are inconclusive, therefore, and must be clarified by additional testing including exercise stress testing, the electrophysiology QT stress test, and genetic testing.

How is LQTS inherited, and who in a known or suspected family should be tested?

LQTS is usually inherited by autosomal dominant transmission. This means that it generally affects both boys and girls equally, and that each child of an affected parent has a 50% chance of inheriting the genetic abnormality. In a really large family, close to 50% of the children would inherit the LQTS-causing genetic abnormality. In average size families, it can range from all to none as each child has an independent 50% chance of inheriting the particular disease gene. Once a family member is identified with LQTS, it is extremely important that other family members be tested for the syndrome. It is especially important to know which parent and grandparent has the abnormality, since brothers and sisters, aunts, uncles, nephews, nieces, and cousins on the affected side are potentially at risk.

This prospective screening, by ECG, is extremely important so that all affected family members are identified and treated early in order to prevent the tragic and unnecessary sudden deaths that may occur.

What about genetic testing?

Genetic testing for LQTS is not the "standard of care" and for other SADS conditions (like CPVT, Brugada, etc.) it is increasingly being used to diagnose and treat people. For people with high QT numbers, the genetic test will help your physician recommend treatment—including possibly an ICD. It will also help your family members to get diagnosed and treated. For people with a "borderline" diagnosis because your QTc number may be low and you have no symptoms, genetic testing can help "rule out" or "confirm" your diagnosis of LQTS.

Your physician will order the initial test on one family member (so-called index case). Once a family member is identified with a gene mutation, testing of other family members for that specific mutation is available, and can assist in clarifying those family members with non-definitive ECG findings. In fact, if a genetic diagnosis of LQTS is established for the index case, the only definitive test to rule in or rule out LQTS for family members and relatives is the LQTS genetic test.

There are two commercial, CLIA-certified labs from which you can order your genetic test: PGx Health and GeneDx. As with any healthcare service, it is always a good idea to be a wise consumer and research each company to see which one might be the better choice for you. Visit www.StopSADS.org for more information.
